

TAN Phase 1 - Natural state-collision experiment: the scalar membrane potential h_t is not a sufficient state variable

(a) Collision at $t = 9$, bifurcation at $t = 10$ under the common probe (Full TAN) and probe x^* , different context: A engages attention, B stays in predictive silence ($S_{10} = 0 \Rightarrow \alpha$ uniform, gate shut)

(c) One-step divergence of all natural collision pairs (per-model ensembles, $\delta = 10^{-4}$)

(d) Attention orthogonalisation drives the current bifurcation (Full TAN)
